

For Immediate release: DataDiscovery Releases Version 1.3 August 14, 2008

DataDiscovery has recently released version 1.3 of DataExaminer. DataExaminer is a new approach to data analysis. Through the correlation of seemingly unrelated files the investigator is aided by not having to remember hundreds, if not thousands, of files that have already been reviewed when new data is added to an existing case or when a new case is started. With DataExaminer files that are added to the data store within the application receive four separate hash values to ensure correlative matches when they exist.

DataExaminer allows the investigator to load files ([see how it works http://www.datadiscoverysoftware.com/Add_Data.htm](http://www.datadiscoverysoftware.com/Add_Data.htm)) from multiple cases while maintaining case integrity for comparative analysis. Through DataCorrelation™ the investigator can and will see when files that are specific to one case appear within that case or exist in a separate case. This may present opportunities for other pieces of the case to be discovered.

In addition to DataCorrelation this latest version introduces Similarity analysis. Along with full indexed key word and string word searches DataExaminer will find any text that is similar to the search results of a key word search but does not contain that specific key word. This enables the investigator to find information that currently goes undetected with other applications.

With version 1.3 of DataExaminer the investigator is no longer restricted to data analysis in a vacuum with just the Single User version. Enterprise Lite and Enterprise configurations are now available allowing for multiple examiners to perform analysis simultaneously. This analysis can be done in multiple languages allowing the investigator to not only have the UI localized but also analyze and perform complex searches on over 40 languages.
